We Protect the Pool Climate and Human Health

APHS Series Indoor Swimming Pool Dehumidification Plant

▶ Why is Humidity Control Important?

At indoor swimming pools, water evaporates because of ambient conditions, pool surface area and pool activities. As a result, bacteria that form in the environment threaten human health and the structure is damaged due to high humidity. Therefore, humidity control at indoor swimming pools where intensive humidity occurs is highly important for facility users in terms of necessary hygienic conditions, human health and lifetime of building. Why Humidity Occurs in Indoor Swimming Pool Areas? If partial pressure of water vapor of ambient air is below saturation temperature then evaporation occurs on surface of pool water. Ambient air temperature and relative humidity, pool water temperature, ambient air movements and pool usage type affect evaporation.

▶ Casing Structure

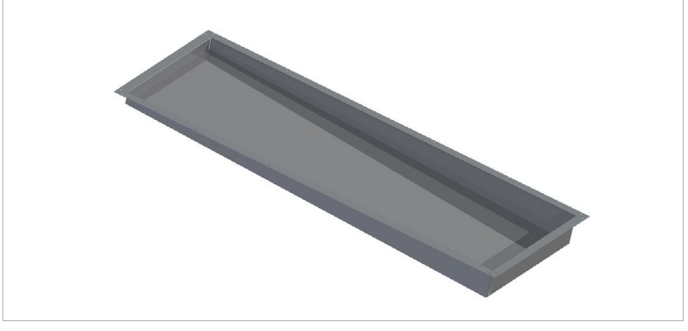
The framed/carcass structure of Airplus Indoor Pool Dehumidification Plant consists of anodized aluminum profiles, anodized aluminum intermediate records, ABS corner and intermediate record connecting parts. With the snap-on design of the profiles, an easy-to-clean environment is obtained by providing a smooth inner surface after panel mounting. Thanks to its special leg design, it is possible to transfer the total weight of the power plant as a distributed load to the ground. To enable horizontal and vertical transport of the device, the base chassis have slots and lifting eyebolts suitable for forklift forks.

▶ Panel Structure

Panel structure in Airplus Indoor Pool Dehumidification Plant is manufactured as double walled and insulated with 70 kg/m3 42 mm rock wool. The thickness of the panel is 42 mm forming a smooth surface on the inner surface of the plant with its snap-on design. The panel thickness can optionally be increased to 50 mm. The inner and outer metal sheets of the panels are manufactured with a thickness of 0,9 mm and painted with oven painted in order to be suitable for working under pool ambient conditions. Thermal bridging and sealing is ensured by using EPDM gasket at the joints of the panel and carcass/ frame.

▶ Pan Structure

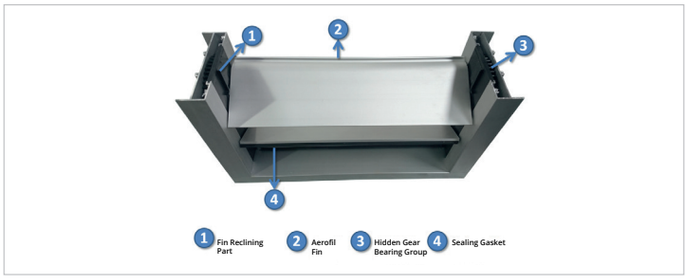
Since the condensation amount is high in Indoor Pool Dehumidification Plants, it is of great importance that this water is discharged quickly and appropriately. Owing to two sloped design trays with 90 mm depth of Airplus Indoor Pool Dehumidification Plant, it is possible to quickly collect and discharge the condensate formed. 1.2 mm stainless steel sheet is used as a tray material. Condensation of the outdoor air is prevented owing to 50 mm rock wool insulation applied under the tray. The standardized leg height of 180 mm provides sufficient siphon height.



▶ Damper Structure

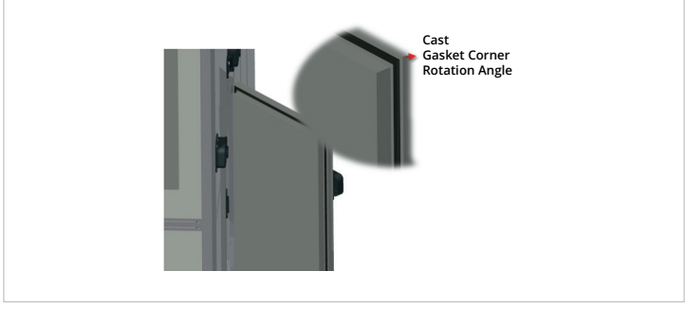
The dampers, made up of specific design aluminum profiles, embody hidden plastic gear structure and bearings. In this way, the moving parts are protected from dust particles coming from the external environment and the system works smoothly.

Minimum pressure loss is provided by preventing distortion of air flow lines with the airfoil design of the damper blades.



▶ Door Structure

Due to the movable structure of the air handling units, doors are of great importance for air leakage. In the doors manufactured from 0,9 mm painted sheet, a spaceless structure was formed by the use of a special cast gasket, thus creating a hermetical structure. Since the corner rotating angles of the used special cast gaskets are calculated, and installation is carried out according to these values, no leakages occur in these regions. A smooth surface is dominant in the interiors by using external gear system as the door handle and the hinge system. The thermal bridges between the indoor and outdoor environments have been eliminated thanks to the significantly important door latches.



▶ The Fan

EC fan complying with ERP Directives is used as the standard in the Airplus Indoor Pool Dehumidification Plant. The body structure is made up of special sheet metal with increased corrosion resistance. It is designed to be highly efficient for the required total air flow and pressure value. Flow control can be ensured depending on the pressure.

▶ The Coil

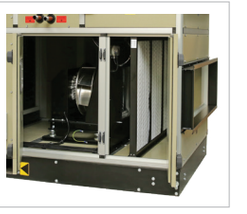
Airplus Indoor Pool Dehumidification Plant includes an evaporator, a heat pipe, a condenser and a water heater Coil. In order to protect against moisture and chlorine, all coils are manufactured with their blades coated with epoxy and hydrophilic coating and the frames are painted. Condensate water is prevented from going to the other cells and channels by using a drop holder following the evaporator with a painted frame made of PP material.

▶ The Heat Pipe

Allows heat transfer between the air, which is required to be conditioned (supply air) and the air, which is required to be evacuated from the environment (exhaust air). When the humidity in the air needs to be removed, this system gives a very big advantage in cases where it is required to maintain a low temperature, then to heat the air again in order not to make too cold blowing. The heat pipe provides convenience and important energy gain in this application. Increases the interior environment air quality. It is easily installed in the air handling unit just as any coil. R134A is used as the refrigerant in the heat pipe.

Pan Structure:	Lamella Coating	Frame Coating
Evaporator	Hydrophilic	Painted
Condenser	Epoxy	Painted
Heat Pipe	Epoxy	Painted
Water Heater Coil	Epoxy	Painted

The general elements of the cycle consist of evaporator, condenser, expansion valve (thermostatic), compressor, solenoid valve, drainer and a bullseye. R407C refrigerator is used as the coolant. The general elements of the cycle consist of evaporator, condenser, expansion valve (thermostatic), compressor, solenoid valve, drainer and a sight glass.R407C is used as refrigerant/ reactor coolant.



▶ Compressor and Cooling Cycle

A scroll compressor is standardized in the cooling cycle used for dehumidification in the AirPlus Indoor Pool Dehumidification Plants.

▶ Filters

G4 class filter is used as the standardized. Special design filter slide mechanism provides easy service. A low depth bag filter can be applied optionally. The filter pressure losses value was calculated based on the formula (clean + dirty)/2. The impurity of the filters can be monitored from the automation system thanks to the differential pressure switches used.

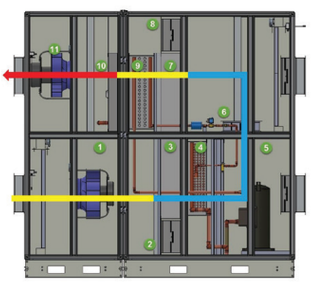
According to ASHRAE HVAC Applications 2015 Handbook, in the Pool Surface Area calculations, the values of 27°C, 30°C 55%, and 1,5 were taken as the references for the Pool Water Surface Temperature, the Environment, and the Activity factor, respectively.

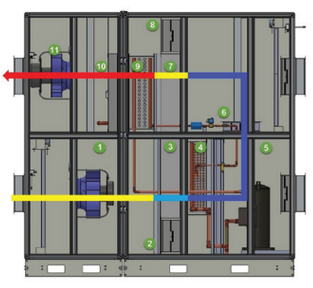
The operating scenario, in which the pool usage rate is low, and the dehumidification process is not applied:

- Heat recovery is active
- The final heater is active when needed
- The suction and blower fan is active at lower air flow
- Cooling circuit off



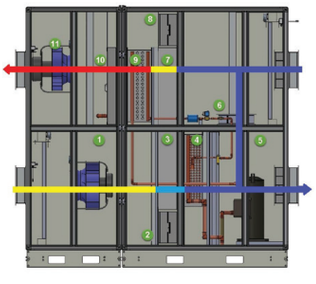
The operating scenario, in which the pool usage rate is low, and the dehumidification process is applied:

- Heat recovery is active
- The final heater is active when needed
- The suction and blower fan is active at lower air flow



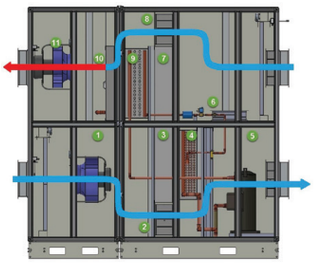
The operating scenario, in which the pool usage rate is high, and the dehumidification process is applied:

- Heat recovery is active
- The final heater is active when needed
- The suction and blower fan is active at higher air flow
- The cooling circuit is active



Mid season (free cooling) operating scenario:

- Heat recovery is off
- The final heater is active when needed
- The suction and blower fan is active at higher air flow
- Cooling circuit off



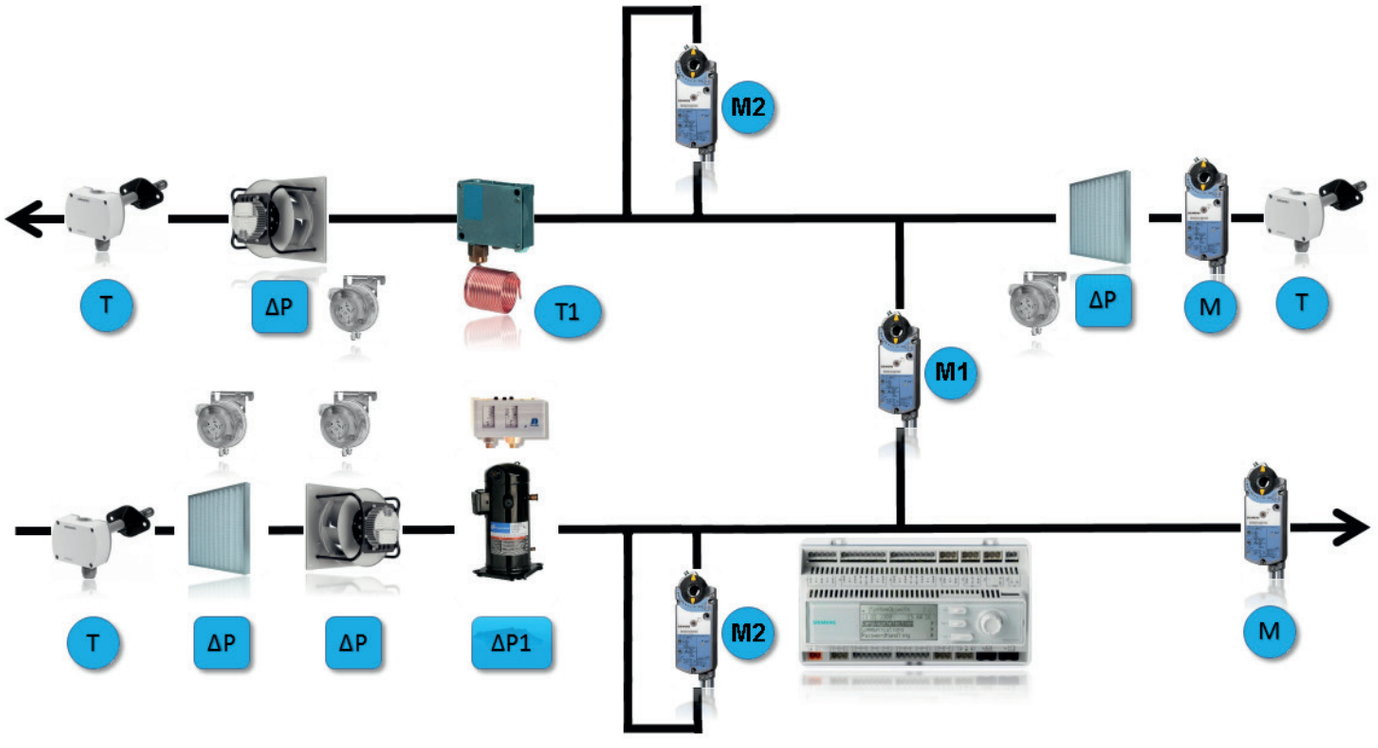
1. Suction Fan
2. Heat Recovery By-Pass Damper
3. Heat Pipe Heat Recovery
4. Evaporator
5. Compressor
6. Mixture Damper
7. Heat Pipe Heat Recovery
8. Heat Recovery By-Pass Damper
9. Condenser
10. Water Heater
11. Blower Fan

Automation System and Flow Diagrams

Airplus Indoor Pool Dehumidification Plant is provided as a package device together with the automation system. By this means, the device can be started-up directly only by making the power connections and the presets. All the automation equipment are positioned in the device and thus protected from external factors.

With the automation system;

- Controlling and monitoring the temperature and humidity values of the external environment, internal environment and blowing.
- Controlling contamination situation of the filters according to the set pressure value.
- Flow control of the EC fans depending on the pressure.
- Proportional controlling and monitoring of the fresh air, return air, and mixture dampers.
- Controlling and monitoring of pressure of the compressor.
- Freezing control of the heater coil.
- Possibility to view all the alarms on the LCD display.
- Can be integrated into building automation systems.
- Possibility to customize the end-user interfaces.
- Possibility to view all functions of the device on the LCD display
- Free Cooling control.
- Automatically detecting and activating determined different operating scenarios.



▶ Technical Specifications
The Evaporation Amount to occur on the Pool Surface, Calculation Example

The need for dehumidification in the pool facilities is caused by human activities, evaporation on the surface of the pool and other external factors. The most important source here is the amount of evaporation that occurs on the surface of the pool. The factors affecting this;

- Ambient air temperature
- Pool water temperature
- Relative humidity of environment
- Amount of air movement
- Pool usage type

- In the Pools with Low Usage: 13 $\left(\frac{g}{hm^2mbar}\right)$
- In the Pools with Medium Usage: 28 $\left(\frac{g}{hm^2mbar}\right)$
- In the Pools with High Usage: 35 $\left(\frac{g}{hm^2mbar}\right)$

Example: The water temperature of a hotel pool with low usage having a surface area of 650 m² is 28°C. The ambient air is 30°C and the relative humidity is %55. Accordingly, calculation of the water amount to evaporate:

$W = e \times A \times (P_B - P_L)$ (According to VDI 2089 Norm),

A: Surface area of the pool (m2)

P_B: The saturated vapor pressure at the water temperature (mbar),

P_L: Partial vapor pressure at the air temperature (mbar),

e: Total vaporization coefficient

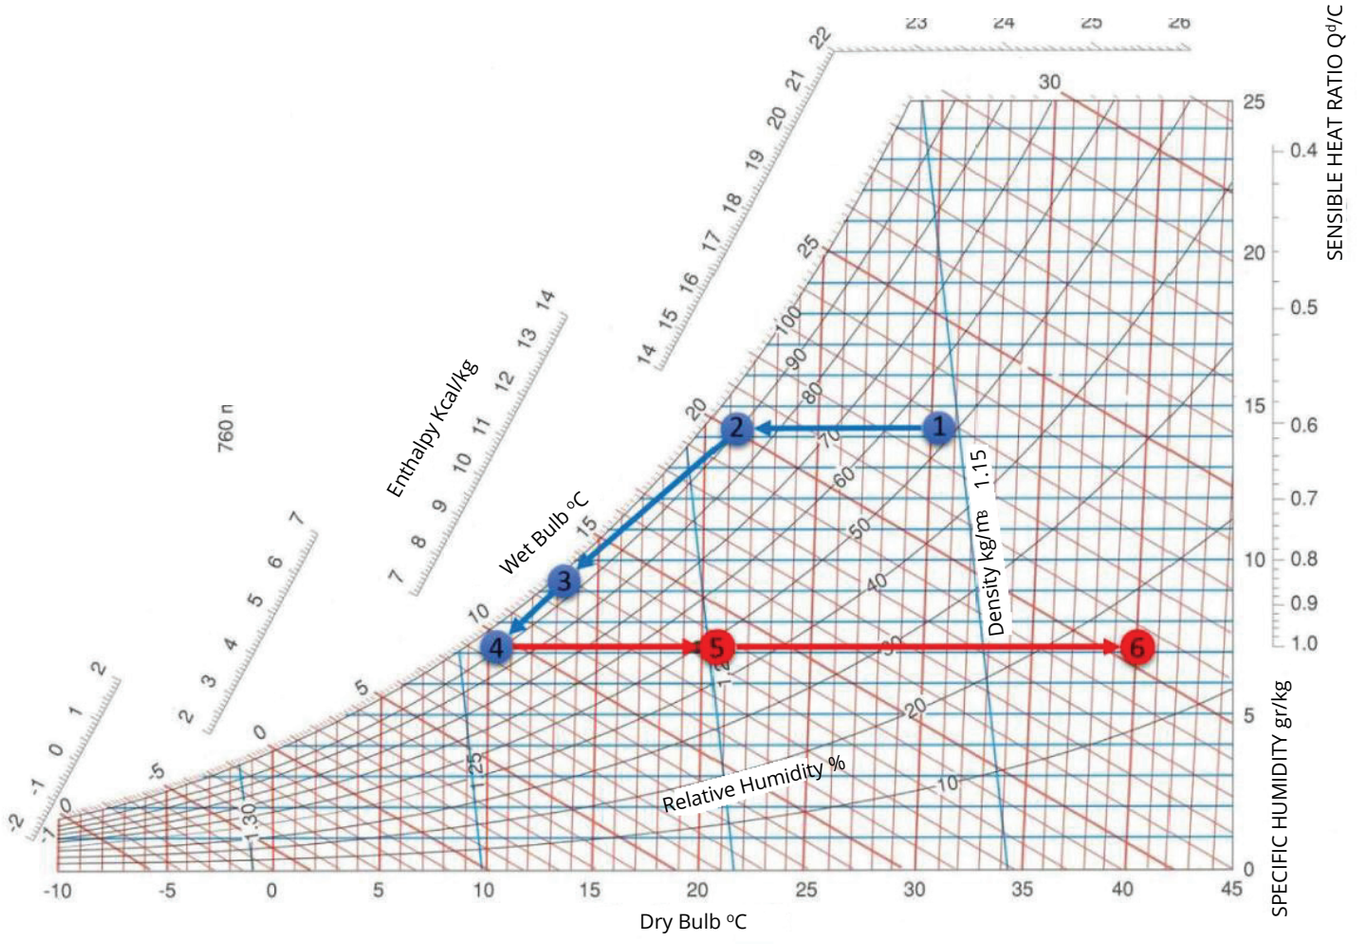
P_B: 38.54 mbarA: Surface area of the pool (m2)

P_L: 23,5 mbar

P_L: Partial vapor pressure at the air temperature (mbar),

e: 13 $\left(\frac{g}{hm^2mbar}\right)$

W = 13 x 650 x (38.54 - 23.5) = 128 kg/h



1-2: Heat Recovery, 2-3: Evaporator, 4: Mixing Point,
4-5: Heat Recovery, 5-6: Condenser
